Keywords: Cognitive Radio, Mobile communication, In-band signalling, Radio link control, common control signalling.

Abstract: Basis of cognitive radio is to exploit unused frequency channels in licensed band. Recently standardised IEEE 802.22 set of cognitive radio protocols envisages fixed and nomadic receivers at below 800 MHz bands. Radio link design for this cognitive radio consider that the channels are available only dynamically to secondary users. Scanning period is thus embedded in link layer control as overhead and reduces overall efficiency of cognitive radio technology. For mobile receivers, availability of permanent channels for radio link control is essential for in-band signalling. Existing mobile communication system uses CDMA 800, GSM 900, GSM 1800 and WCDMA 2000 MHz bands for which approximately 1/8th of the band capacity is used for in-band signalling. Present work provides an assessment of vacant channels in mobile communications range which were permanently available at the time of measurement. The study used conventional Radio frequency scanners available for different bands and dedicated engineering handsets for tracking active frequencies. Observations were taken at six different cities of India with population ranging from 1.5 million to 6.6 million. The tests were performed with assemblies carried in a vehicle and across the length and breadth of each city. The allotment of frequencies by Frequency Regulatory Authority to local mobile operators along with the frequency bands reserved for further distribution were also considered. The experimentally collected data were analysed using RF analysis software and spread sheet database. An analysis of the collected data lead to arrive at the conclusion that more than 1/8th part of resources of each band are nearly

permanently vacant which is enough to design in-band common control signalling methods for cognitive radio.

I. INTRODUCTION

The continued success of mobile wireless industry is placing more demands on an already scarce and valuable radio frequency resources banking on commercially successful technologies. Regulators of every country put an eye to oncoming recommendations arising out of standardization institutes and mark corresponding blocks as reserved for future licensing. This has been added up with continued demand for higher bandwidth due to data and video. As a result, one most promising technology has come up for efficient spectrum utilization of the unused channels in the licensed band termed as Cognitive Radio (CR). Cognitive Radio users are termed as secondary users whereas licensed users are termed as primary users. Since secondary user uses the same band as that of a primary user, the former has to take care that the later one is not (or minimum) disturbed in terms of access and interference. CDMA in 800 MHz band, GSM at 900MHz and 1800 MHz bands, WCDMA in 2000MHz band, LTE in 2300 MHz band and WiMAX at 2500MHz and 3500MHz bands are dominant players in mobile communication radio. Wi-Fi and other low power radios play at ISM band at 2400MHz band. To give space to a demanding frequency channel of a band to a primary user, secondary user has to keep track of all the vacant channels of all bands and their respective qualities in terms of SNR and throughput. Thus, cognitive radio users deploying opportunistic spectrum access has to scan continuously the whole range of spectrum with a

reasonable bandwidth and scanning frequency. This is a very cumbersome and computing intensive mechanism. Alternatively, a scanner which scans only predefined channels of specified bandwidths and across licensed mobile radio frequency bands only, shall be very efficient and trustworthy. Matched filtering and coherent detection technique is most suitable in such environment for its short detection time, high SNR, low probability of missed detection and false alarm [1]. Matched filtering closely resemble to SDR compatible Mobile Station (MS) available commercially and also in digital RF scanner used for drive test purpose. Also, most of the communication system needs a pilot and dedicated control channels which remains as fixed during the entire period of communication between two users. This needs association of a permanent frequency channel with cognitive radio, preferably in-band hired channel along-with primary users or select a channel out of band. In opportunistic spectrum access, secondary users will use licensed spectrum when primary users do not transmit. According to Beibei Wang and K J Ray Liu, availability of such a global control channel is not realistic since there may be no permanent channel available for secondary users [2]. Probability to get an opportunistic control channel in licensed band for all nodes in cognitive radio network has been narrated as dramatically small by Antonio De Domenico and co-authors [3]. Thus, exploration for availability of Quasi-permanent channels in licensed mobile communication bands for cognitive radio shall truly facilitate with the advantages of working with common control channel in MAC layer. In the present study, the licenses allocated to mobile service providers of India has been taken into consideration for estimation of grossly available vacant channels of reserve bands and drive tests were conducted in six different cities for completely allocated GSM bands. It was established that more than one-eighth part of all bands are vacant which closely resembles to the requirement of one signaling channel for seven traffic channels.

The remainder of the paper is organized as follows: Section II explains the signaling channel part requirement as a fraction of channel capacity for mobile communication technology systems which enable us to draw empirical statement for access of the whole licensed band by cognitive radio. Section III covers literature survey indicating the availability of channels in different commercial bands. Section IV discusses about the reserve spectrum and actual allotment of channels by the spectrum allocation authority. Section V describes the measurement plan and collection of data at different cities. This is followed by presentation and discussion of the collected results in Section VI. Finally, the conclusions are presented in Section VII.

II. EMPIRICAL STATEMENT

Regulatory Authorities of every country identify frequency bands for public mobile communication technologies e.g. CDMA, GSM, WCDMA, WiMAX etc. Each band is divided into radio frequency (RF) channels for license purpose. Based on technology deployed, operators divide each RF channel into communication channels which consists of common control (CC) channels and data (traffic) channels. Common Control channels services traffic channels and are within licensed RF i.e. in-band. In 800 MHz band, CDMA IS-95 uses 1.25MHz bandwidth as communication channel with one pilot and seven common control channels i.e. total 8 channels out of total 64 Walsh code channels. Walsh code count was 128 for CDMA 2000 1x i.e. one RF. In 1x EV-DO there are 8 control channel time slots out of total 256 time slots and 96 chips of pilot is embedded in each data slot of 1024 chips which together counts for $1/8^{\text{th}}$ part of the channel. In WCDMA, out of total radiated power of 20Watts, primary and secondary control channels and pilot channels constitutes 2.585 Watts leaving 17.415 Watts for traffic. In GSM, if there is one RF, the first time slot works as the pilot and common control channel for remaining 7 time slots. In case of 2 or more RFs, on an average, one time slot of first RF is used as control channel for each additional RF. In OFDMA, for a 5 MHz channel, there are 60 pilot sub-carriers for 360 data sub-carrier and 92 null sub-carriers and thus the ratio is slightly higher than $1/8^{\text{th}}$ part of the whole RF channel.

Thus, approximately $7/8^{\text{th}}$ part of a licensed RF channel of a frequency band is available for useful communication and the remaining part is used for control purpose. As a corollary of the above, we can say that $7/8^{\text{th}}$ part of a band is used for purposeful data communication and remaining $1/8^{\text{th}}$ part for common control and signaling purpose. Alternatively, if $1/8^{\text{th}}$ part of a frequency band is permanently available as spare and the same is used for common control purpose, the total band can be completely accessed for cognitive radio communication purpose.

III. LITERATURE SURVEY

A survey was conducted in Barcelona, Spain [4] to carry out a broadband spectrum measurement campaign which covered the frequency range from 75MHz to 3GHz in an outdoor urban environment. The measured frequency range was divided into six consecutive 500 MHz blocks. Each block was measured during a continuous period of 48 hours and was observed that only 22.57% of the whole frequency range between 75MHz and 3GHz was occupied. A similar type of survey was conducted in Singapore [5] to find the spectrum usage pattern in frequencies from 80 MHz to 5.85 GHz. The 24-hour measurement had been taken at

the roof top of Institute for Infocomm Research's building over 12 weekday periods, which indicated that the average occupancy on the frequency range from 80 MHz to 5.85 GHz was only about 4.54%. In a survey at the Loring Commerce Centre [6], the measurements were made during a normal work week for 3 days for the frequency ranges between 100 MHz to 3 GHz. Based on the results of the study, it was observed that the average spectrum usage during the measurement period was 1.7%.

The static measurement shows that the mobile licensed bands and ISM bands are partly occupied and the remaining parts of the spectrum resembles noise. It is apparent that no study has been made to assess actual occupancy of mobile communication bands based on measurements at different locations of the same city in licensed band. Also, no study has been made to find

variation of channel occupancy for different type of cities. These studies shall help us to accurately identify the frequency channels with low or no active utilization and successfully deploy them in cognitive radio technology.

IV. RESERVE SPECTRUM AND ALLOCATION

In India, the radio frequencies are being used for different types of services like mobile communication, broadcasting, radio navigation, satellite communication, defense communication, etc. The National Frequency Allocation Plan (NFAP) forms the basis for development and manufacturing of wireless equipment and spectrum utilization in the country. Frequency bands allocated to various types of mobile communication services in India are mentioned in Table I.

TABLE I
LICENSED BANDS OF DIFFERENT WIRELESS TECHNOLOGIES

Technology used	Band and Channel Width	Technology Bandwidth in MHz	*Allocation	*Occupancy/Remarks
CDMA	890-915MHz; 935-960MHz; Channel B/W 1.25MHz FDD; 20 channels	25+25	5 Operators – 2 RF each	50% vacant
GSM 900MHz	824-849MHz; 869-894MHz; 124 channels of 200 kHz spacing	25+25	4 Operators	Fully Licensed- vacant channels to find out experimentally
GSM 1800 MHz	1710-1785MHz; 1805-1880MHz; 374 channels	75+75	4 Operators	60% vacant channels; actual to find
WCDMA	1920-1980MHz; 2110-2170MHz	60+60	3 Operators – 5 MHz each	75% vacant channels
WiMax & 4G	2500-2690MHz	190	3 Operators- 15 MHz each	77% vacant channels
WiMax (fixed)	3400-3600MHz	200	One -20MHz	90% vacant channels

*As per available information.

So far CR technology has been developed keeping into consideration that all channels in licensed bands are dynamically accessed and released. Game theory is applied for capturing a vacant channel inviting competition amongst CR operators. Further, there is a possibility of occupying a vacant band by CR secondary user in the guise of a primary user. In addition, a concept of bidding for vacant channels has also come up for use by secondary users at a comparative cost. All these factors introduces the concept of business out of the unused channels of a licensed user with or without having a permanent infrastructure for CR. It is thus envisaged that mainly public authorities providing public utility services at almost zero cost may be authorized to operate over unoccupied spectrum even though licensed. However the number of such public utility service providers is expected to be very limited. Table I clearly indicates that one out of total eight communication channel in each band is permanently available as vacant

for using as pilot and signalling purpose which is necessary for the working of Cognitive Radio communication except GSM 900 MHz band. Conduction of field test is absolutely necessary for assessment of quasi-permanently vacant channels for use of in-band common control signalling purposes.

V. MEASUREMENT SETUP AND DATA COLLECTION

The measurement setup used is a drive test equipment which performs tests in a cellular network and collects data on a moving vehicle. The software and hardware used are: Laptop with charger and USB hub, GPS and data cable, Digital RF Scanner, License dongle for TEMS, Cell site database and Link budget, Clutter diagram from Google website, MapInfo software, Engineering handsets with 4 (2G/3G) SIMs of different operators mounted simultaneously and cable terminal. In

the setup, data collection software is installed in the laptop which uses a mobile phone along with GPS system. Drive test route was carefully selected and data was collected accordingly. GPS collects the data of latitude and longitude of each point while mobile collects data like signal strength, uplink and downlink frequency, etc. All the information is stored with their respective date and time as well as their geographical locations. File sizes are kept within limit of about 25MB in each part trace and a new file is open in each part. Data from all part files are grouped from collection software and are stored in some output file. Using the above setup, measurement was taken on six cities at different geographical locations viz. Kolkata, Patna, Ranchi, Dibrugarh, Jaipur and Bhopal which have population ranging from 1.5 million to 6.6 million shown in Table 2.

Figure 1 shows the measurement route map of Jaipur. Jaipur city has a population of about 6.66 million. One side of measurement route is heavily populated while it is less populated on the other side. The lower band of frequency channels is distributed among three operators while the upper band is allocated to one operator. While moving from location having 75.82894°E and 26.91442°N , it is found that in lower band of Operator1 - 14 BCCH are occupied namely 71,73,75,76,77,78,80,81,82,87,88,111,112,113 while 29 BCCH are vacant (72,74,79,83 to 86,89 to 110) of which BCCH no. 89 to 110 is not used at all. Among hopping channels, two hopping channels 114 and 121 are vacant. While in Operator2, 13 BCCH (1 to 13) and 18 hopping channels (14 to 31) are fully occupied. In Operator3, 13 BCCH (50 to 62) and 18 hopping channels (32 to 49) are also fully occupied. The frequency band is switched to upper band used by Operator 4, in which 15 BCCH (530 to 544) and 15 hopping channels (546 to 560) are occupied while one BCCH number 545 is vacant. So, on an average 75% of frequency spectrum of lower band is utilized.

Figure 1. Measurement Route map of Jaipur

Kolkata is a densely populated city which has a population of about 4.48 million in core Municipal area.

During the survey, the area selected was busiest one which has tall buildings towards right side at North and scattered single storied structure towards the river. Towards South, it is almost green field; measurement route is shown in Figure 2, it is found that the lower band and upper band of frequency channels is distributed among three operators. In the two operators of lower band in Kolkata all the BCCH viz. 70, 71,73 to 76, 78,80,82,87,88,111,112,113 in Operator 1 and 50 to 62 in Operator 2 are fully occupied but 30 BCCH i.e. 72,77,79,81,83 to 86, 89 to 110 are vacant in third operator; and 4 hopping channels i.e., 40,48,49,96 are vacant. In the upper band only one BCCH, i.e., 873 is vacant among the three operators; while no hopping channels are available. In Kolkata, it is found that average spectrum occupancy is about 72.58%.

Figure 2. Measurement Route map of Kolkata

VI. RESULTS AND DISCUSSION

Figure 3. Population Spectrum Graph

Data was also collected for spectrum occupancy measurements in GSM at 900MHz bands in an outdoor environment other cities viz. Bhopal, Patna, Ranchi and Dibrugarh. Figure 3 depicts the spectrum occupancy in six cities of India. In Bhopal, the spectrum occupancy in lower band is 74.19% while in Ranchi it is only 52.42% as it switches to upper band where it has a spectrum occupancy of 83%. The measurements shows that the

spectrum occupancy in lower band of Patna is 75.8% where as in Dibrugarh is 75%.

TABLE II POPULATION SPECTRUM CHART

S.No.	City	Population (in millions)	% Spectrum Occupancy
1	Bhopal	2.36	74.19
2	Patna	1.68	75.8
3	Kolkata	4.48	72.58
4	Ranchi	2.91	52.42
5	Jaipur	6.66	75
6	Dibrugarh	1.5	75

The obtained results demonstrated the existence of significant amounts of spectrum potentially available for the future deployment in CR networks in lower bands of GSM which are not at all used.

VI. CONCLUSIONS

Discussion from above reveals that more than 20% of the completely licensed bandwidth is practically vacant in a saturated market environment. This is well above the requirement of $1/8^{\text{th}}$ part of the band to get access to the whole of the bandwidth at a time by cognitive radio and adequate to take additional MAC level overhead required for Cognitive Radio. There is no immediate necessity of these channels by the licensed operators which can be safely deployed as common control channel for cognitive radio purpose. Further, to doubly enhance protection of common control channel, a disaster recovery common control channel may be designated which will hold the replica of allotments and processing status of CR Primary Common Control Channel. Use of commercially stable technologies with minimum changes at Operator Transceiver equipment and user mobile equipment for adaptation to Cognitive Radio technology shall lead development of a economically deployable system.
